Assay of Residual PPA.HCl Content
of GITS Recovered from Stools

INTRODUCTION

The following is a description of a high pressure liquid chromatographic method for the determination of phenylpropanolamine.HCl (PPA.HCl) content in OROS®. The determination involves crushing the systems and dissolving the particles in distilled water, and injecting a filtrate of this solution into the chromatographic system. The compound is resolved on a reverse phase column and detected by UV absorption at 254 nm. Quantification is obtained by linear regression analysis of peak areas of a standard curve containing at least three standard points. Results will be reported as the HCl salt of PPA. This assay will resolve PPA from α -aminopropiophenone.

SAMPLE PREPARATION

Accurately weigh (mg) each system, then place each system between two plastic weigh boats and crush with a rubber mallet. Quantitatively transfer the crushed system particles to a 250 ml volumetric flask and add about 100 ml distilled, deionized water. Place the volumetric flask in a sonic bath for 10 minutes, to dissolve the drug particles. Cool to room temperature, then fill each flask to volume with H₂O and mix. Filter a portion from each flask and inject 40 mcl into the chromatographic system.

STANDARD PREPARATION

For analysis of systems containing 75 mg of drug, accurately weigh about 60 mg PPA.HCl USP Reference Standard, or equivalent, and transfer quantitatively to a 50 ml volumetric flask.* Fill to volume with H₂O and mix. Prepare working standard dilutions by accurately pipeting the following volumes of PPA.HCl standard stock solution and H₂O into appropriate glass test tubes, and mix. Assuming 60 mg PPA.HCl was used to prepare the standard stock solution, the following calibration standards would be generated:

| <u>PPA.HCl Stock</u> <u>(ml)</u> | <u>H₂O</u> <u>(ml)</u> | <u>Final Volume</u> <u>(ml)</u> | <u>PPA.HCl</u> <u>(mg/ml)</u> |
|-------------------------------------|--------------------------------------|------------------------------------|----------------------------------|
| 1.00 | 5.00 | 6.00 | 0.200 |
| 1.00 | 3.00 | 4.00 | 0.300 |
| 1.00 | 2.00 | 3.00 | 0.400 |

Prepare standards daily prior to analysis.

*NOTE: For analysis of systems containing other than 75 mg of drug, divide the expected (labeled) system PPA.HCl content by 75. Then, multiply the product by 60 to get the amount of PPA.HCl needed to prepare a stock solution that, when diluted as suggested above, will bracket the expected sample concentration.

Appendix III
(continued)

ANALYSIS

Assemble a liquid chromatograph employing a controlled volume pumping system, a sample injection device, a UV detector capable of detection at 254 nm and a suitable recorder and/or integrator. Use the chromatographic column as indicated.

EQUIPMENT

Pump: Waters 6000 A or equivalent
Detector: Waters M440 or equivalent
Injector: Waters WISP 710 A or B Automatic Sample Processor, or Rheodyne 7105, or equivalent.
Column: Waters Micro Bondapak C₁₈ 10 micron or equivalent.
Recorder: mV output matched to detector output
Integrator: Spectra Physics 4100, or equivalent

OPERATING PARAMETERS

Flow Rate: 1.5 ml/min
Pressure: 2500 psig
Detector Wavelength: 254 nm
Chart Speed: 0.2 in/min or 0.5 cm/min
Injection Volume: 40 µl
Column Temp: Ambient
Attenuation: 0.05 AUFS
Retention Time: PPA 7.4 min (nominal)

Appendix III (continued)

REAGENTS

Mobile Phase: 40:60 MeOH:buffer

Prepare as follows:

To a 1 liter volumetric flask add 700 ml distilled H₂O, 50 ml of 1 M NaH₂PO₄, pH 7, 1.9 g Hexane Sulfonate Na, and 20 ml of 0.25 M triethylammonium phosphate, pH 7.3: Fill to volume with H₂O and mix. Transfer contents to a 2 liter erlenmeyer flask and add 667 ml MeOH. Mix and degas by vacuum filtration.

COLUMN PERFORMANCE

Assemble the specified chromatographic system. To condition the column, set the monitoring wavelength and pass mobile phase through the column at the flow rate to be used for analysis. Equilibrate the system until a steady baseline is obtained and column pressure is stabilized. If repeated sample injections give a stable retention time, proceed to analyze the samples and record the actual conditions used for the analysis.*

*NOTE: If α -aminopropiophenone is to be quantified, inject an aliquot of a test mixture prepared by adding 0.1 ml of α -aminopropiophenone Stock Standard¹ to 9.9 ml of one of the PPA·HCl calibration standards. If a resolution factor of greater than 1 is obtained, proceed to analyze the sample preparations.

CALCULATIONS

IDENTITY

Identify the PPA peak (and, α -aminopropiophenone peak, if present) by comparison of the retention time of the sample preparation(s) with that of the

¹Prepare a Stock Standard of α -aminopropiophenone·HCl as follows: .

Weigh 25 mg of α -aminopropiophenone·HCl USP Reference Standard, or equivalent, and quantitatively transfer to a 50 ml volumetric flask. Dissolve and fill to volume with distilled water. If α -aminopropiophenone is detected in sample preparation(s), then dilute this Stock Standard with 0.05 M phosphate buffer, pH 6.5, to obtain 1, 2, 4, and 6 mcg/ml of α -aminopropiophenone·HCl working standards.

Appendix III
(continued)

standard preparation(s). If the retention times match, sample peaks are identified.

CONCENTRATION

Construct a standard curve by plotting concentrations (mg/ml) of PPA·HCl vs. peak area on linear graph paper, or by calculating the best straight line by linear regression analysis. Measure the peak area of the Sample Preparations and determine the concentration of PPA·HCl in the samples from the standard curve. Then calculate:

A. $\text{mg PPA}\cdot\text{HCl in system} = C \times 250 \text{ ml}$

B. $\text{Wt \% PPA}\cdot\text{HCl in system} = \frac{C \times 250 \text{ ml}}{W} \times 100\%$ where

C = concentration of sample solution obtained from standard curve, in mg/ml

W = weight of system, in mg

- C. From the individual assay results above, calculate the average drug content and standard deviation

NOTE: The same calculation may be used for quantifying α -aminopropiophenone using a standard curve obtained from the working standards suggested on pg. 3. Additional working standards may be prepared to bracket the detected concentration of α -aminopropiophenone in the sample preparation(s).

PHENYLPROPANOLAMINE ABSORPTION DURING ORAL ADMINISTRATION
FROM GASTROINTESTINAL THERAPEUTIC SYSTEMS - STUDY 2

OBJECTIVE: To compare the bioavailability and the profiles for plasma levels and total urinary excretion for the following three oral dosage forms of phenylpropanolamine:

- (1) Acutrim OROS capsules
- (2) Dexatrim 12 hour sustained release capsules.
- (3) Aqueous solution

DESIGN: Twelve subjects received 75 mg PPA HCL per day from one of the oral dosage forms indicated above, for four consecutive days during weeks one, three, and five of the study, according to a 3 x 3 Latin square design. Blood samples were drawn during days one and four of the dosing cycle and assayed for phenylpropanolamine HCL. Urine was collected during the entire dosing cycle.

STATISTICAL METHODS: The following parameters were analyzed by analysis of variance (Grizzle)¹:

Area under the curve for day one

Area under the curve for day four

Total urinary excretion.

In addition, Westlake's confidence intervals² were calculated for each pair of dosage forms for these three parameters.

Plasma levels were also analyzed by a repeated measures analysis of variance (ANOVA)³. This analysis tests the null hypothesis of equality of all formulation means, as well as parallelism of the

response curves over time (formulation by time interaction).

Comparisons between formulations at each time point were made using Student's t tests.

Since the ANOVA table for the repeated measures analysis contains three "error" terms (main plot error, subplot error, and the subject by time interaction), appropriate error terms for performing the tests at each time point were constructed as linear combinations of the main plot and subplot mean squares⁴.

RESULTS AND CONCLUSIONS: There were no significant differences among the three oral dosage forms for bioavailability as measured by area under the curve at day four ($p=0.12$). For day one, the area under the curve for Dexatrim was significantly higher than both Acutrim and aqueous solution ($p=0.036$), but there was no significant difference between Acutrim and the aqueous solution ($p>0.05$). Significant differences in the shapes of the plasma concentration time curves are indicated by the highly significant formulation by time interaction (Table 2) and the plot of mean plasma levels (Figure 1 and 2). These differences can also be seen from the comparisons of the three formulations at each time point as presented in Table 1.

Statistics Report
(ST-144-83)

PHENYLPROPANOLAMINE ABSORPTION DURING ORAL ADMINISTRATION
FROM GASTROINTESTINAL THERAPEUTIC SYSTEMS - STUDIES 1 AND 2

OBJECTIVE: To compare the bioavailability and the profiles for plasma levels for the following three oral dosage forms of phenylpropanolamine:

- (1) Acutrim OROS capsules
- (2) Dexatrim 12 hour sustained release capsules
- (3) Aqueous solution

DESIGN: In study one, six subjects received 75 mg PPA HCL per day from one of the oral dosage forms indicated above, for four consecutive days during weeks one, three, and five of the study, according to a 3 x 3 Latin square design. Blood samples were drawn during day one, at 48 hours, and on day four of the dosing cycle and assayed for phenylpropanolamine HCL.

In the second study, twelve subjects were included. This study was essentially a replication of the first, although there were some minor differences in blood sampling times.

STATISTICAL METHODS: The following parameters were analyzed by analysis of variance (Grizzle)¹:

Area under the curve for day one

Area under the curve for day four.

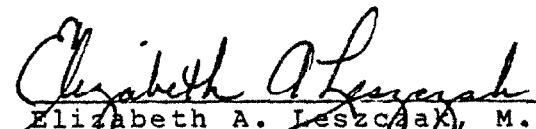

In addition, Westlake's confidence intervals² were calculated for each pair of dosage forms for these two parameters.

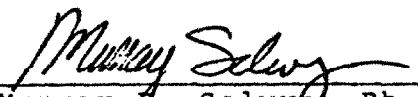

Plasma levels for those time points common to the two studies were also analyzed by a repeated measures analysis of variance

(ANOVA)^{3,4}. This analysis tests the null hypothesis of equality of all formulation means, as well as parallelism of the response curves over time (formulation by time interaction). Comparisons between formulations at each time point were made using Student's t tests. Plasma values indicated as "<6.2" were taken to be zero in all analyses. Mean values for all time points are presented in Table 1 and Figures 1 through 3.

Since the ANOVA table for the repeated measures analysis contains several "error" terms, appropriate error terms for performing the tests at each time point were constructed as linear combinations of the main plot and subplot mean squares^{5,6}.

RESULTS AND CONCLUSIONS: There were no significant differences among the three oral dosage forms for bioavailability as measured by area under the curve at day one or day four ($p > 0.05$). Significant differences in the shapes of the plasma concentration time curves are indicated by the highly significant formulation by time interaction (Table 2) and the plot of mean plasma levels (Figures 1, 2 and 3). These differences can also be seen from the comparisons of the three formulations at each time point as presented in Table 1.
